# 1 Introduction

## 1.1 Problem Summary

Caddy is a robot entered into the 2005 Roborodentia. Roborodentia is an annual autonomous robotics competition held during Cal Poly's Open House by the IEEE Computer Society. Robot entries must navigate a maze searching for three randomly placed golf balls, collect them, and then deposit the balls in the "nest" at the end of the maze. The 2005 competition also included a new aspect. Two bonus balls were placed on a platform behind the wall in two predetermined corners of the maze such that the top of the golf ball was flush with the top of the wall.

Figure 1: Arena map showing the two fixed bonus ball locations and the potential locations of the randomly placed ground balls

The competition scoring breakdown is as follows:

Point Value	Task
1	Passing the first turn in the maze - Point A
1	Triggering "nest" solenoid by activating optical sensor - Point X
3	Touching each ground ball (1 point per ball)
3	Collecting and possessing each ground ball (1 point per ball)
3	Bringing each ground ball to "nest" - Area B (1 point per ball)
9	Placing each ground ball in "nest" - Point E (3 points per ball)
10	Collecting and possessing a bonus ball - 2 Yellow Balls (5 points per ball)
6	Placing a bonus ball in the "nest" (3 points per ball)
36	Total possible points

In the case of a tie, the robot with the fastest time wins.

## 2 Goals and Requirements

The rules of the competition dictated a baseline set of goals that need to be met to be successful:

- **Line following** - The corridors of the maze were constructed with a black electrical tape line down the center, meant as an aid for the autonomous navigation of the pathways - and we saw no reason not to take advantage of it.
- **Junction detection** - To navigate the maze, Caddy would need the ability to detect when a junction was reached and to identify the type of junction (e.g. "T" junction, straight-or-right-turn junction, etc).
- **Ground ball collection** - The maximum score without collecting any ground ball is 5 out of 36 possible points - so a ground ball collection system is a must to score well.
- **Bonus ball collection** - Since the scoring distribution weighted bonus balls so heavily (16 of the 36 possible points are awarded for bonus ball tasks), we also decided that Caddy would need bonus ball collection capability in order to be competitive.
- **Ball release-into-nest system** - For an additional 3 points per ball, having the ability to release balls into the nest seemed worthwhile and comparatively simple to implement.

In addition to this baseline set of goals, we decided to focus on the autonomous aspect of the Roborodentia competition. In particular we wanted a robot that could *actively adapt* to the random ball locations (unlike any previous entry had ever done). This was the driver for an additional two requirements:

- **Path planning** - Caddy needed a way to map the arena and a shortest path algorithm that could find the best path through a sequence of goals.
- **Ball finding** - To make the best use of the path planning algorithm, we needed a way to actively search for balls down untraveled corridors.

## 3 Design

### 3.1 Collaborative Team Process

The team for this project was formed from interested members of the the [Cal Poly Robotics Club](#).

To organize the tasks and identify critical paths in the (short) project time line, we used [GanttProject](#) to create a Gantt chart.

For code control and collaboration we used Concurrent Versions System (CVS). Since this project had a competitive nature, we chose to setup and host our own private CVS server rather than use a free, Internet-based hosting service.

Between face-to-face team meetings we used Drupal to host a private forum for discussing ideas, sharing progress, etc.

The inline code documentation and this project report were both managed using [Doxygen](#). Keeping the documentation in plain text and means that the documentation can be version controlled the very same way as the source code. The documentation also tends to stay more up to date since it can be more conveniently updated at the same time as the source code.

### 3.2 System Architecture

When taking a holistic look at the project goals and requirements, it is clear that a camera-based vision system can satisfy line following, junction detection and ball-finding requirements. The image processing required for these task can all be done with a camera that is low resolution, low power, and low cost. The ball finding task, in particular, has few other options that are both low cost and simple to implement. The [CMUcam2](#) developed by students at Carnegie Mellon University and sold through distributors as a packaged vision system, met our needs well.

Since the CMUcam can handle all the computationally intensive image processing as well as drive 5 servo control outputs, our requirements on the main microcontroller were fairly relaxed. The most computationally demanding task for the main microcontroller is the shortest path algorithm, but with a relatively small map even this could be handled by a low-end microcontroller.

Figure 2: Electronics block diagram

### 3.3 Electrical Design

#### 3.3.1 Power Regulation and Motor Controller

We opted to design and build our own power regulation and motor control circuitry over purchasing one of the more expensive off-the-shelf solutions. To ensure that we were not debugging software and electrical issues at the same time (difficult!) made sure to include robust regulation and decouple in the design. Our power sub-component power needs were:

- +5V regulated power for the ATmega32 and the rest of the electronics
- +6-15V unregulated power for the CMUcam2
- +6V for each motor, controllable via logic-level signal

Unregulated voltage was connected to the CMUcam2 (it had a built-in regulator) and to the motors. Although not ideal, connecting the motors to unregulated power meant we could save on cost by using a smaller, cheaper voltage regulator. We opted for a linear regulator to supply the +5V to the ATmega32 microcontroller.

In the choice between a linear regulator and a switching regulator, a linear was chosen over a switching regulator for the following reasons:

- Lower output noise - We wanted to take every precaution we could to ensure the EMF voltage generated by the motors did not affect the electronics.
- Simpler to implement - Switching regulators typically require more passive components to filter the inherently higher noise they generate.
- Cheaper

Switching regulators are more efficient, however any efficiency gains would be dwarfed in comparison with the power demands of the unregulated components (DC motors and CMUcam2). The circuit diagram for our implementation is shown below:

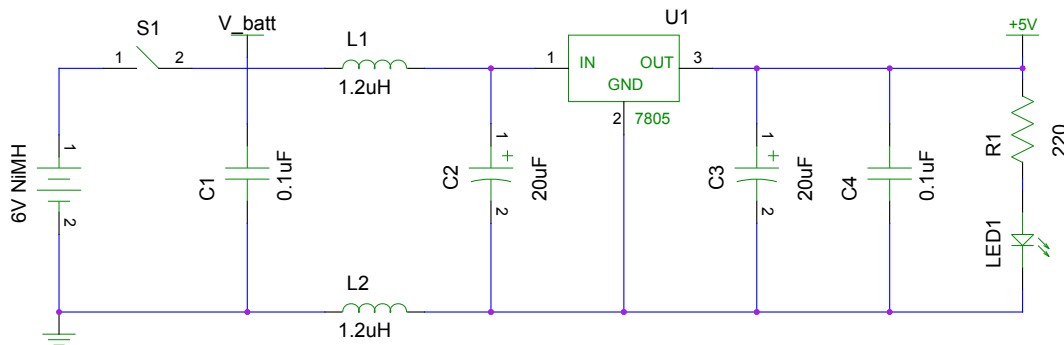

Figure 3: Power regulation circuit

To control the motors via digital signal we used an H-bridge circuit. For added protection of the electronics from the back-EMF voltage of the motors, additional diodes were connected as shown in the schematic below.

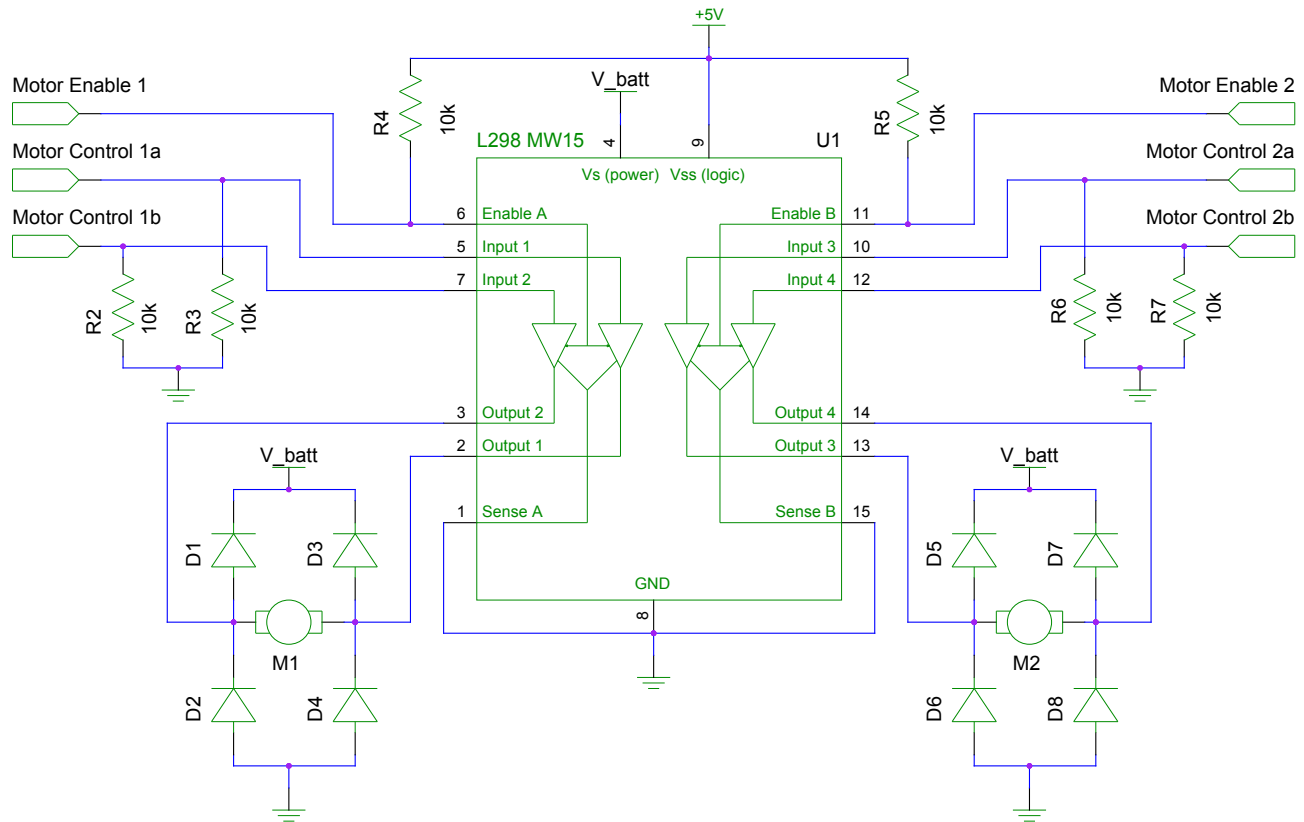

Figure 4: Motor control circuit

The power regulation and motor control circuits were fabricated together on a single board using a copper-plated board, etching solution, and a laser print out of the circuit layout. We made sure to use polarized headers for all the connections to avoid making any reverse polarity mistakes (we still managed to make a couple!).

### 3.3.2 IR Break Beam

In order to capture ground balls, Caddy needed a way to detect when a ball was within the grasp of its lift mechanism.

Originally planned to use the centroid tracking feature of the camera since the camera would always be facing down for line tracking during the times it needed to detect ground balls. This turned out to be difficult mainly due to the limitations of the camera. When the camera is configured to track a black line, glare from the overhead lighting and red golf balls have the same effect on what the camera detects – a gap in the line. We tried to simply change modes whenever a gap was detected, determine if the gap was due to a glare or a due to a ball, and then act accordingly. Unfortunately, the CMUcam did not handle rapid mode and parameter changes well, taking too long to switch from one mode to another. This led to a failure in our carefully tuned PID line tracking algorithm which relied on frequent, regular updates over time. We considered and experimented with some ways of solving this problem but none were the quick, elegant solution we were looking for.

With a fast approaching deadline, we opted for a quick, but less elegant, solution. We installed an IR break beam sensor looking across the front of the lift arm so that when the arm was down and fully open a ground ball would break the beam as it passed under the arm.

### 3.3.3 Servo Reverser

The mechanical design of Caddy required 6 servos:

- Ball pickup, left side
- Ball pickup, right side
- Boom control
- Ball hopper
- Tilt action
- Pan action

This meant that the original plan to use the five servo control outputs of the CMUcam would be inadequate.

The following approaches were considered for accommodating the 6th servo output:

- **Mechanical:** Modify the mechanical design so that the ball pickup mechanism could be controlled by just one high-torque servo. The lift mechanism had already been iteratively refined to the point that it could be actuated by just one mechanical motion. Going this route would likely mean some major rework of the mechanical design - not ideal since we were otherwise happy with the mechanics of the robot.
- **Software:** Use some of the extra pins on the ATmega32 to generate a servo PWM signal. Unfortunately we were already using the two PWM peripherals on the ATmega32 so we would have to do this in software. We had limited timer resources on our chip and weren't sure how we might need to use them in the future so this was not an ideal solution.
- **Electrical:** Leverage the fact that the 2 servos controlling the ball pickup were the same signal, 180 degrees out of phase. This seemed like a perfect application for a simple 555 timer circuit.

Searching the Internet, we found we were not the only ones to think of using a 555 timer to create a servo reverser. Using the well documented plans from C. Dane [1] we fabricated a board the size of a postage stamp.

### 3.3.4 Wheel Encoders

The maneuvers needed at junctions and for the bonus ball pick up sequences needed to be accurate and repeatable. To achieve this we used a black and white encoder disk that we printed out and glued to the inside edge of each drive wheel. [2]

Figure 5: Reflective IR wheel encoder pattern

### 3.4 Software Architecture

#### 3.4.1 Computing Platform

For our computing platform we chose an ATmega32 microcontroller from Atmel's 8-bit AVR line of microcontrollers because it was C-programmable with free open-source tools and because we had a readily available development board, the ERE EMBMega32.

Figure 6: EMBMega32 development board from ERE CO.,LTD

#### 3.4.2 PID Line Tracking

To track the black electrical tape line, we implemented a proportional–integral–derivative (PID) controller. In PID theory, the output of a PID controller,  $c(t)$ , is defined as:

$$c(t) = P_E e(t) + P_I \int e(t) dt + P_D \frac{de}{dt}$$

Where  $e(t)$  is some error function and  $P_E$ ,  $P_I$ , and  $P_D$  are adjustment coefficients for the observed error, the integrated error and the derivative of the error, respectively. We define our error term:

$$e(t) = \frac{dx}{dt}$$

By substitution, we get:

$$c(t) = P_E \frac{dx}{dt} + P_I x(t) + P_D \frac{d^2x}{dt^2}$$

Broken down and interpreted for the task of line tracking, these terms are:

- $P_E \frac{dx}{dt} \leftarrow$  How fast are we drifting from the center line?
- $P_I x(t) \leftarrow$  How far are we from the center line?
- $P_D \frac{d^2x}{dt^2} \leftarrow$  How fast is the drift rate accelerating?

Provided that there is a way to measure or compute each of these terms, this is a more robust form of the equation because it eliminates the integral term which can cause problems due to accumulated error.

The figure below shows how the camera was used to measure  $P_E \frac{dx}{dt}$ :

Figure 7: Diagram of line tracking geometry (NOT to scale)

The drift rate is the slope of the black line with respect to the center line of the robot. For points  $P_1 = (x_1, y_1)$  and  $P_2 = (x_2, y_2)$  from the diagram above we define:

$$\frac{dx}{dt} = \frac{y_2 - y_1}{x_2 - x_1}$$

And for point  $P_3 = (x_3, y_3)$  with constant, measurable value for  $y_3$  and for constant, measurable line center  $x_{center}$

$$x_3 = x_{center} - \frac{dx}{dt}(y_3 - y_1) + x_1;$$

Lastly, by storing the previously computed value of  $\frac{dx}{dt}$ , we can compute the third term:

$$\frac{d^2x}{dt^2} = \frac{dx}{dt} - \frac{dx}{dt}_{previous}$$

The coefficients for each of these terms were determined by trial and error using a tethered remote and stored persistently in EEPROM.

### 3.4.3 Maneuvering

When turning our bot by a certain number of ticks, we experienced overshoot despite actively applying DC motor braking. We addressed the problem with the following software solution.

After turning for the desired number of ticks, we applied braking and counted the number of excess ticks that occurred from the instant braking was commanded. After a fixed delay, we drove the wheels in the opposite direction for that same number of ticks.

This worked well for the most part, however, with different battery charges, turn amounts, and turn types, the amount of time to brake was never the same. If we did not brake the motors for a long enough delay, our bot would stop counting excess ticks and begin to drive the motors in the opposite direction, too soon. With our unsophisticated encoders that cannot detect the direction of wheel motion this resulted in "reverse ticks" being counted before the wheel had actually started moving in the reverse direction.

### 3.4.4 Ball Detection and Localization

### 3.4.5 Path Planning

## 4 Conclusion

### 4.1 Future Work

#### 4.1.1 Regulated Motor Voltage

If we end up working with higher voltage motors again, it may be worth losing some voltage in order to send regulated voltage to the motors. This allows for more consistent operation across fresh and low batteries. This should also condition our batteries better, because the battery voltage can drop until the regulator's threshold is reached. As long as we drop the voltage down enough, it should be obvious when batteries are dead. As the regulator cuts out, the bot should slow down more dramatically. A common solution in ME 405 (mechatronics) is to regulate 14.4V down to 12V with an adjustable regulator (LM1084) for each motor. One regulator was not able to provide enough current for both motors. When driving the motors at the same pulse width, we were able to see a difference in how straight the bot drove, if the motors received voltages a few hundredths apart. Yet, just having the ability to precisely and consistently set the voltage to the motors was very useful.

## 4.1.2

Since we were using timer 1 (a 16-bit timer) for PWM, we could have used 16-bit PWM. 8-bit resolution seemed to be sufficient with the original 6 volts motors, but when we switched to 12 volt motors, more precise control of the PWM signal would likely have improved the PID line tracking. As it was, we had to use a PID offset constant of 1 which means that we would have required division to decrease the proportional coefficient parameter of our PID control algorithm.

## 4.1.3 Quadrature Wheel Encoders

Quadrature wheel encoders would have required more mechanical work (to mount the reflective IR sensors 90 degrees out-of-phase) and electrical work (wiring for twice as many sensors) but it would have helped solve some challenges with maneuvering the robot through precise sequences such as the bonus ball pickup.

Quadrature encoders would have allowed us to perform overshoot correction easily and accurately.

## 5 Appendix

### 5.1 Gantt Chart

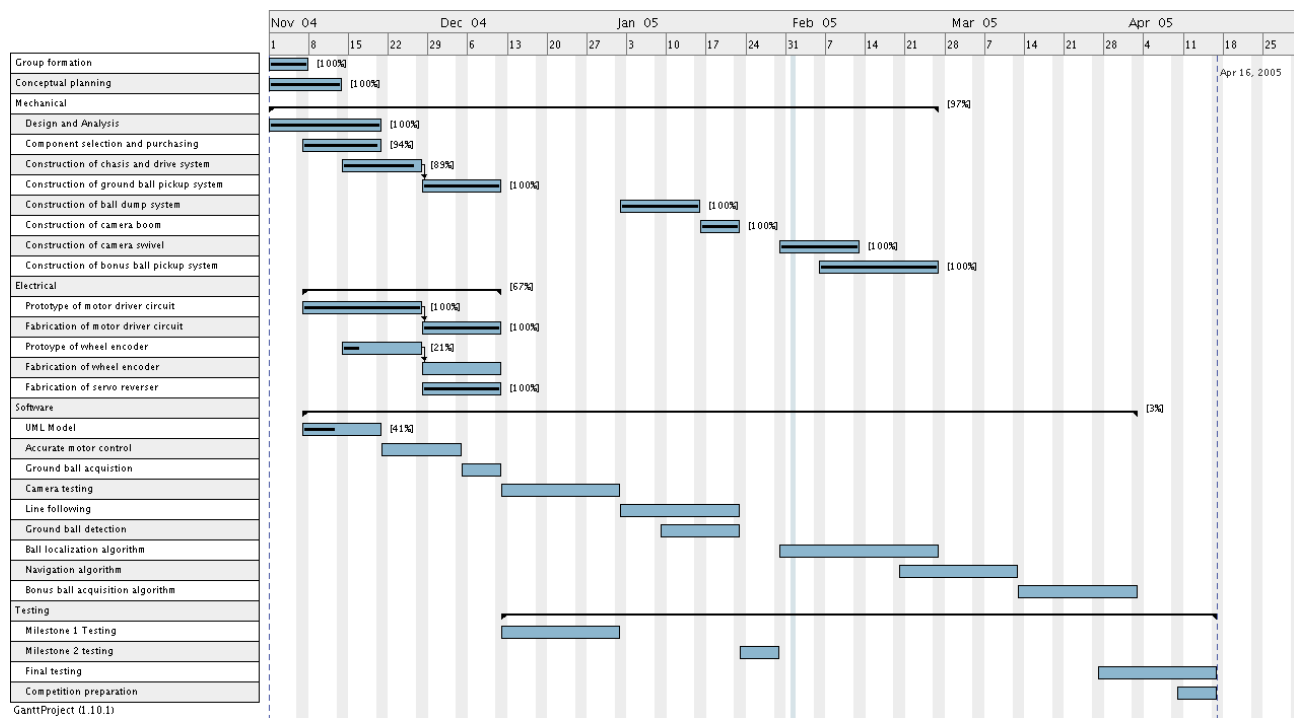

Figure 8: Caddy project gantt chart

### 5.2 Individual Contributions

Caddy was a joint effort between Taylor Braun-Jones, Logan Kinde, Tyson Messori, Scott Barlow, Michael Shelley, and Patrick McCarty. Primary contributors were Taylor, Logan, and Tyson.

Figure 9: Team Photo. Left to right: Logan Kinde, Tyson Messori, Taylor Braun-Jones, Scott Barlow, Michael Shelley, Patrick McCarty

### 5.2.1 Contributions of Taylor Braun-Jones

Taylor was responsible for overall project coordination and administration including:

- Gantt chart creation and tracking
- MESFAC grant proposal
- Part ordering and budget management
- Creation and administration of the code repository

Taylor's electrical and mechanical contributions include:

- Custom-made battery packs from shrink wrap and five +1.2V rechargeable NiMH AA batteries
- The design and implementation of the bracket used to mount the CMUcam2 to the panning servo
- The concept and implementation of a detachable tethered remote for debugging and run-time parameter adjustment

The software contributions are attributed as follows:

- Code structure, high level architecture, and build system - Taylor Braun-Jones
- Path planning algorithm and implementation - Logan Kinde
- EEPROM reading and writing - Patrick McCarty
- PWM motor controller - Michael Shelly

The rest of the code and the majority of the code base was developed between Taylor and Logan together using the [pair programming](#) technique. These pieces include:

- PID line tracking
- Ball detection and seeking
- Course traversal
- Ball collection maneuvers

### 5.3 Acknowledgments

This project was made possible by a generous \$525 grant from the Cal Poly Mechanical Engineering Student Fee Allocation Committee (MESFAC) and from various part and monetary contributions of the the Cal Poly Robotics Club.

## 6 Data Structure Index

### 6.1 Data Structures

Here are the data structures with brief descriptions:

### 9.11.1 Detailed Description

Definition in file [camera.c](#).

### 9.11.2 Function Documentation

#### 9.11.2.1 void `cameraWhiteBalance` ( void ) [inline]

Optimize the white balance for current conditions.

Turn auto-white balance on, give it time to settle, then turn auto-white balance off.

00018 //
00019 //
00020 // File Name : 'encoder.h'
00021 // Title : Quadrature Encoder reader/driver
00022 // Author : Pascal Stang - Copyright (C) 2003-2004
00023 // Created : 2003.01.26
00024 // Revised : 2004.06.25
00025 // Version : 0.3
00026 // Target MCU : Atmel AVR Series
00027 // Editor Tabs : 4
00028 //
00029 // Description : This library allows easy interfacing of quadrature encoders
00030 // to the Atmel AVR-series processors.
00031 //
00032 // Quadrature encoders have two digital outputs usually called PhaseA and
00033 // PhaseB. When the encoder rotates, PhaseA and PhaseB produce square wave
00034 // pulses where each pulse represents a fraction of a turn of the encoder
00035 // shaft. Encoders are rated for a certain number of pulses (or counts) per
00036 // complete revolution of the shaft. Common counts/revolution specs are 50,
00037 // 100,128,200,250,256,500,etc. By counting the number of pulses output on
00038 // one of the phases starting from time0, you can calculate the total
00039 // rotational distance the encoder has traveled.
00040 //
00041 // Often, however, we want current position not just total distance traveled.
00042 // For this it is necessary to know not only how far the encoder has traveled,
00043 // but also which direction it was going at each step of the way. To do this
00044 // we need to use both outputs (or phases) of the quadrature encoder.
00045 //
00046 // The pulses from PhaseA and PhaseB on quadrature encoders are always aligned
00047 // 90 degrees out-of-phase (otherwise said: 1/4 wavelength apart). This
00048 // special phase relationship lets us extract both the distance and direction
00049 // the encoder has rotated from the outputs.
00050 //
00051 // To do this, consider Phase A to be the distance counter. On each rising
00052 // edge of PhaseA we will count 1 "tic" of distance, but we need to know the
00053 // direction. Look at the quadrature waveform plot below. Notice that when
00054 // we travel forward in time (left->right), PhaseB is always low (logic 0) at
00055 // the rising edge of PhaseA. When we travel backwards in time (right->left),
00056 // PhaseB is always high (logic 1) at the rising edge of PhaseA. Note that
00057 // traveling forward or backwards in time is the same thing as rotating
00058 // forwards or backwards. Thus, if PhaseA is our counter, PhaseB indicates
00059 // direction.
00060 //
00061 // Here is an example waveform from a quadrature encoder:
00062 /*
00063 //
00064 // Phase A:      /---\ /---\ /---\ /---\ /---\ /---\
00065 //              |   | |   | |   | |   | |   | |   |
00066 //              ---/ \---/ \---/ \---/ \---/ \---/ \-
00067 // Phase B:      \---\ /---\ /---\ /---\ /---\ /---\
00068 //              |   | |   | |   | |   | |   | |   |
00069 //              \---/ \---/ \---/ \---/ \---/ \---/
00070 // Time:         <----->
00071 // Rotate FWD:   >----->
00072 // Rotate REV:   <-----<
00073 */
00074 // To keep track of the encoder position in software, we connect PhaseA to an
00075 // external processor interrupt line, and PhaseB to any I/O pin. We set up
00076 // the external interrupt to trigger whenever PhaseA produces a rising edge.
00077 // When a rising edge is detected, our interrupt handler function is executed.
00078 // Inside the handler function, we quickly check the PhaseB line to see if it
00079 // is high or low. If it is high, we increment the encoder's position
00080 // counter, otherwise we decrement it. The encoder position counter can be

```

```

00080 // read at any time to find out the current position.
00081 //
00082 //

00018  /*******
00019  //
00020  // File Name : 'encoderconf.h'
00021  // Title : Quadrature Encoder driver configuration
00022  // Author : Pascal Stang - Copyright (C) 2003-2004
00023  // Created : 2003.01.26
00024  // Revised : 2004.06.25
00025  // Version : 0.2
00026  // Target MCU : Atmel AVR Series
00027  // Editor Tabs : 4
00028  //
00029  // The default number of encoders supported is 2 because most AVR processors
00030  // have two external interrupts. To use more or fewer encoders, you must do
00031  // four things:
00032  //
00033  // 1. Use a processor with at least as many external interrupts as number of
00034  // encoders you want to have.
00035  // 2. Set NUM_ENCODERS to the number of encoders you will use.
00036  // 3. Comment/Uncomment the proper ENCx_SIGNAL defines for your encoders
00037  // (the encoders must be used sequentially, 0 then 1 then 2 then 3)
00038  // 4. Configure the various defines so that they match your processor and
00039  // specific hardware. The notes below may help.
00040  //
00041  //
00042  // ----- NOTES -----
00043  // The external interrupt pins are mapped as follows on most AVR processors:
00044  // (90s8515, megal61, megal63, mega323, megal6, mega32, etc)
00045  //
00046  // INT0 -> PD2 (PORTD, pin 2)
00047  // INT1 -> PD3 (PORTD, pin 3)
00048  //
00049  // The external interrupt pins on the processors megal28 and mega64 are:
00050  //
00051  // INT0 -> PD0 (PORTD, pin 0)
00052  // INT1 -> PD1 (PORTD, pin 1)
00053  // INT2 -> PD2 (PORTD, pin 2)
00054  // INT3 -> PD3 (PORTD, pin 3)
00055  // INT4 -> PE4 (PORTE, pin 4)
00056  // INT5 -> PE5 (PORTE, pin 5)
00057  // INT6 -> PE6 (PORTE, pin 6)
00058  // INT7 -> PE7 (PORTE, pin 7)
00059  //
00060  // This code is distributed under the GNU Public License

## 9.35.1 Detailed Description

Course defined by a connected grid of nodes. Conserves SRAM by storing graph of arena in FLASH memory. See doc directory for image of arena with node numbers.

- Nodes are represented by numbers:
  - Nodes 0 and 42 are terminal nodes
  - Nodes 1-20 are ball nodes
  - Nodes 21-41 are junctions
- Distance resolution is 6 inches. -Direction is measured in binary radians or brads. (see [www.urcp.com](http://www.urcp.com))

Version History: 2/17/05 - Created by Logan 2/21/05 - Checked by Logan, Scott, and Patrick

- Changed syntax for Atmel - Logan
- Added more defines - Logan 4/11/05 - Re-structured for FLASH - Logan

Definition in file [nodeList.h](#).

## 9.37 perms.h File Reference

Iterative (non-recursive!) permutation generator.

```
#include <stdint.h>
#include <stdbool.h>
```

Include dependency graph for perms.h: This graph shows which files directly or indirectly include this file:

### Functions

- bool [generateNextPermutation](#) (uint8\_t \*first, uint8\_t \*last)  
Reorder an array of values to the next higher permutation.

#### 9.37.1 Detailed Description

Iterative (non-recursive!) permutation generator.

Definition in file [perms.h](#).

#### 9.37.2 Function Documentation

##### 9.37.2.1 bool generateNextPermutation ( uint8\_t \* first, uint8\_t \* last )

Reorder an array of values to the next higher permutation.

The "next higher" permutation is the one that is lexicographically one step higher than the input order. The order that would compare smaller to all other permutations is the one in which all elements are sorted in ascending order. This is the initial order that should be used in order to cycle through all possible permutations.

Typical usage example:

```
uint8_t myArray[] = { 1, 2, 3 };
do {
    // ... do something with current permutation of myArray
} while (generateNextPermutation(myArray, myArray + 3);
```

#### Remarks

This iterative permutation generation algorithm was taken, with slight modifications, from the GNU implementation of the C++ STL (libstdc++). It was chosen for its lower memory usage over simpler and more common recursive implementations.

#### Returns

true if the next higher permutation could be generated, false otherwise

Definition at line 22 of file [perms.c](#).

### 9.39 tetherUI.h File Reference

Simple user interface to change parameters without reprogramming.

This graph shows which files directly or indirectly include this file:

#### Macros

- `#define NAV_LCD_MODE 0`
- `#define LINE_LCD_MODE 1`

## Functions

- void `runTetherUI` (void)  
*Allow tweaking via tether remote until red button pressed.*

### 9.39.1 Detailed Description

Simple user interface to change parameters without reprogramming. The user interface is implemented as push buttons and LEDs on a small solder-less breadboard connected to Caddy using CAT5 cable and RJ-45 connector for quick and easy attach/detach.

Definition in file [tetherUI.h](#).

### 9.39.2 Macro Definition Documentation

#### 9.39.2.1 `#define LINE_LCD_MODE 1`

Special LCD display mode for debugging line tracking

Definition at line 36 of file [tetherUI.h](#).

#### 9.39.2.2 `#define NAV_LCD_MODE 0`

Default LCD display mode

Definition at line 31 of file [tetherUI.h](#).

```

## 9.43 trackColor.h File Reference

Simple tracking Roborodentia objects of interest by color.

```

#include <stdint.h>
#include <stdbool.h>

```

Include dependency graph for trackColor.h: This graph shows which files directly or indirectly include this file:

## Macros

- `#define LOOK_RIGHT 1`
- `#define LOOK_LEFT -1`
- `#define LOOK_UP 0`
- `#define MX_NDX 0`
- `#define MY_NDX 1`
- `#define X1_NDX 2`
- `#define Y1_NDX 3`
- `#define X2_NDX 4`
- `#define Y2_NDX 5`
- `#define PIXEL_CNT_NDX 6`
- `#define CONFIDENCE_NDX 7`
- `#define NUM_COLOR_STATS 8`
- `#define PAN_SEEK_OFFSET 66`

## Functions

- void **trackColorInit** (int8\_t dir)
- uint8\_t **getBallY** (void)
- bool **seeBall** (void)
- bool **cameraSeekLeft** (uint8\_t uncheckedBalls[][2], uint8\_t numUncheckedBalls)
- bool **cameraSeekRight** (uint8\_t uncheckedBalls[][2], uint8\_t numUncheckedBalls)

## Variables

- volatile bool **colorStatsProcessed**
- bool **inSeekPosition**

## 9.43.1 Detailed Description

Simple tracking Roborodentia objects of interest by color. Uses the CMUcam2 color blob tracking to:

- Identify ball and estimate distance from robot
- Identify nest
